PRACTICAL # 01

Installing Unix/Linux

Before you start installing Red hat Linux, You should know the **pre-requisites** for the same i.e. the system requirements

System Requirement for Red Hat Linux 5

Parameters	Requirements
CPU Type	Pentium 4 or higher, 2GHz or higher
Memory/RAM	1 GB minimum, upto the system limit
Hard Disk	4 GB minimum

Steps to install Red Hat Linux 5

Insert the RHEL DVD into the machine and boot from it. The below page which you see is the first which comes on the screen.

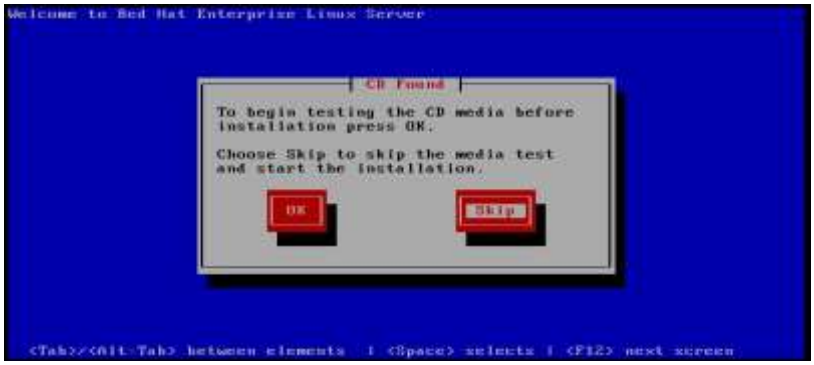

This is the prompt which can be used to

- Install using GUI (Graphics Mode)
- Install using CLI (Text Mode)
- Upgrade your RHEL version
- Boot into Rescue Mode

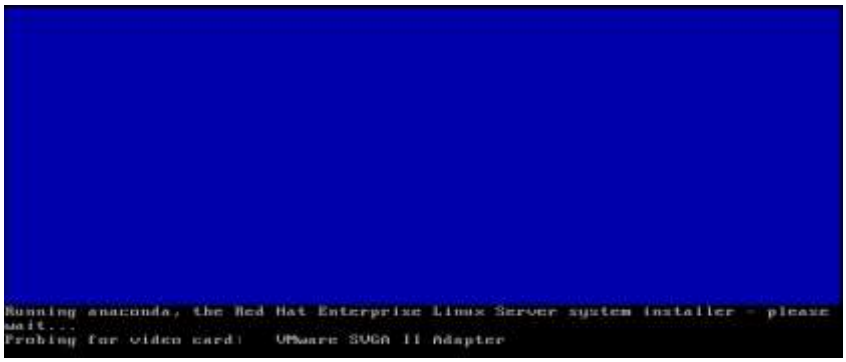

Hit **Enter** and by default installation will begin using GUI setup

The next screen prompts you to verify the content of the DVD used. If you believe the DVD you are using is correct and not corrupt, you can skip this step as I did

As you see in the next step anaconda installer starts which is used to install Red Hat Linux and many other similar OS like Fedora, CentOS

Click Next to start the installation

Select the preferred Language for installation, as for me it is English

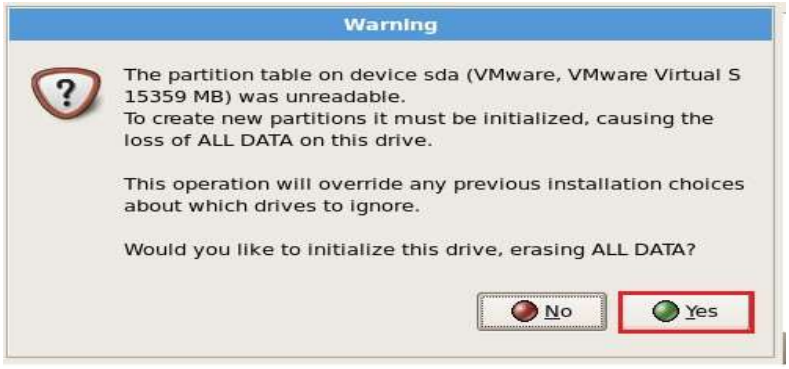

Select the keyboard Language you are using on your machine. (For most by default it is US or US International)

If you have a authorized installation no. provided by Red Hat, you can enter in the below shown box. As of now I don't have any such key so I will skip this step

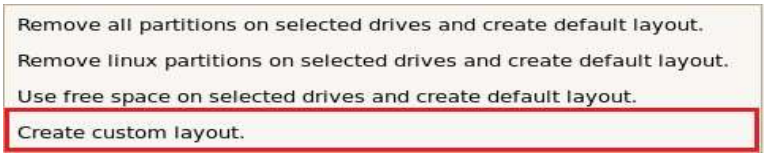

Click **YES** to format the hard disk

Using the drop down arrow as shown below you can select the available options for creating partitions

As of now I will go with the "**Create custom layout**" option

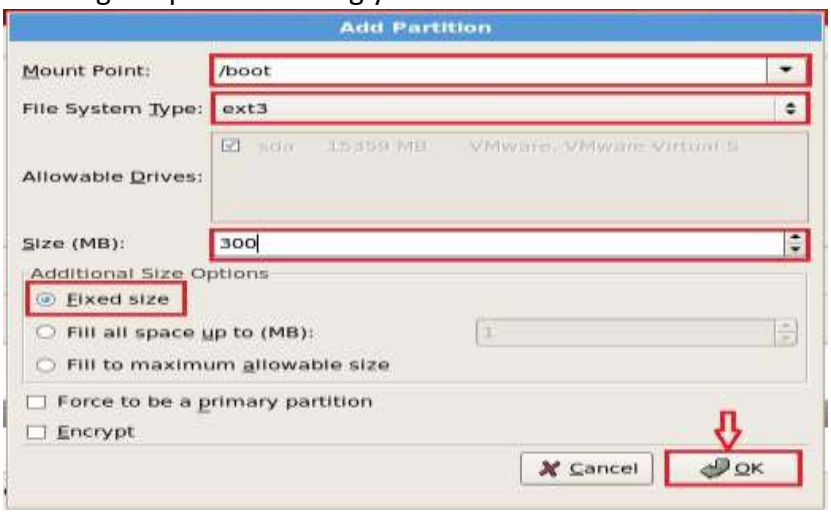

The next screen shows you the available space on the disk along with any other available partitions. In my case I am installing on a fresh machine so it shows all the space as free.

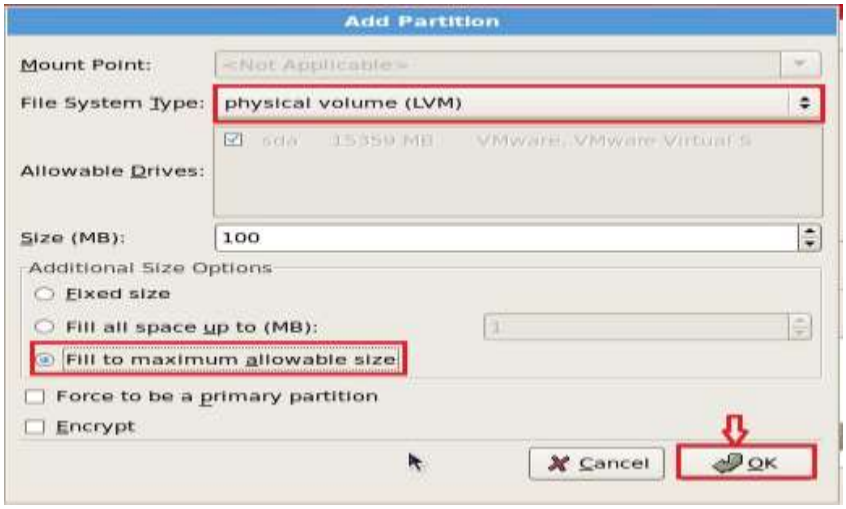

Click on **New** to create partition

Create **/boot** partition as shown below. The maximum expected boot size is not more than **200300 MB**. So you can give space accordingly

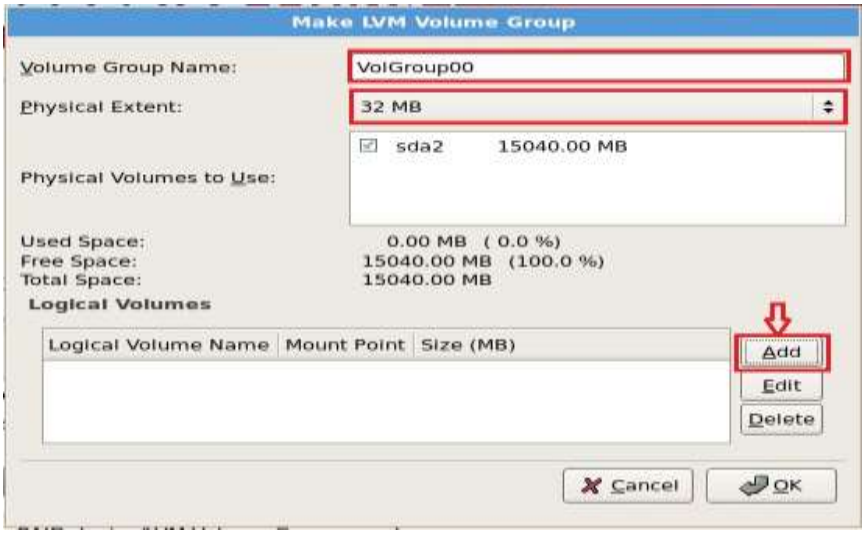

Now again select **New** and create a LVM partition of all the available hard disk as shown below. Select the options as shown in **RED**

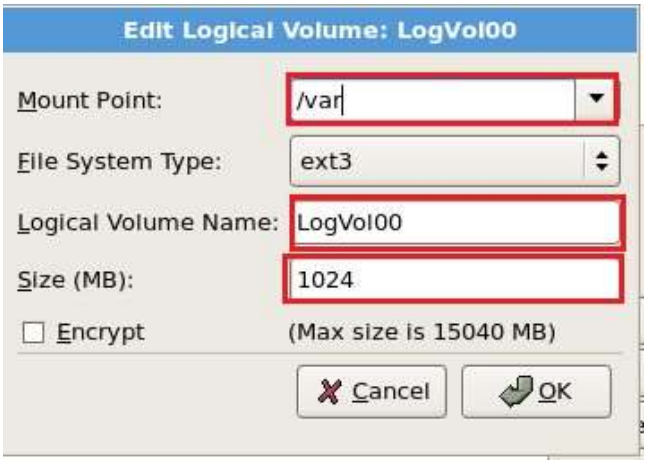

Select **LVM** option

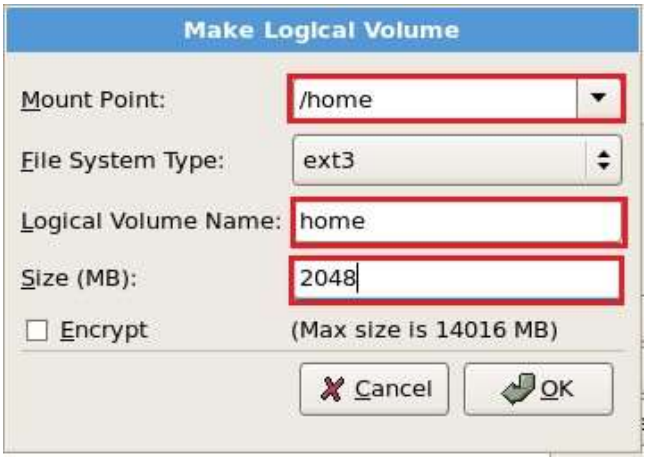

Now a new window will pop up where you can give a Volume Group name as per your requirement.
Next click on Add as shown below to create other LVM partitions such as root, home, var, tmp as per your requirement.

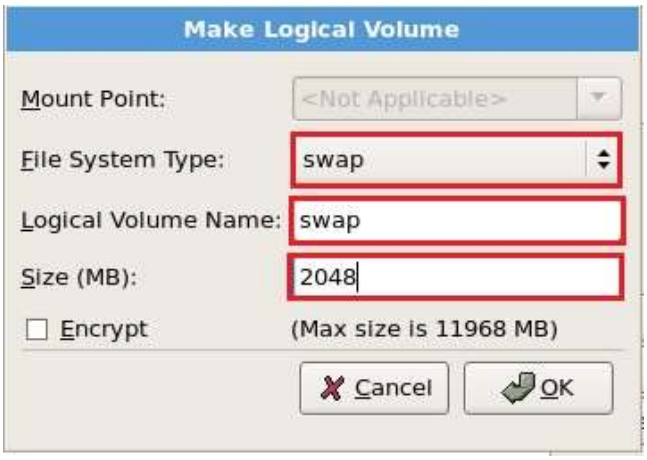

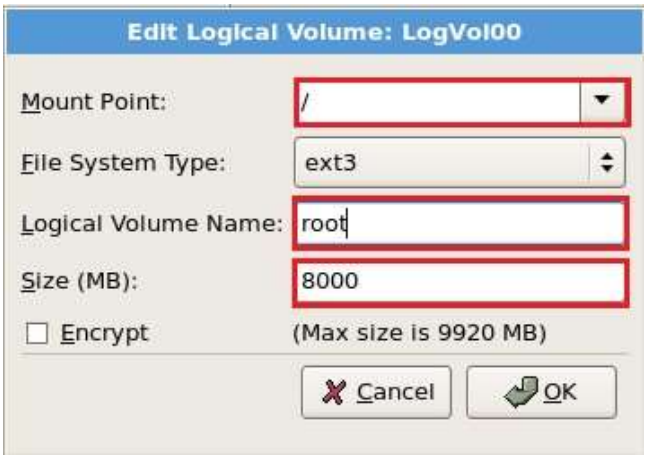

Create the required partitions and allocate the space to each partition as shown in below screenshots

Create a swap partition. No mount point required for it. Just select a file system type as swap and allocate the size. For our case 2048 MB

Once done click on **Next** and move to the next screen

From here there are two methods to configure networking.

- DHCP method
- Static method

For DHCP follow the below screenshot

Using DHCP

For static method follow the below screenshots

Using Static I

Using Static II

Next screen will ask for the region you are installing your server. For me it is **INDIA** for which I will select **Asia/Kolkata** as shown below

Provide a password

Select Customize Now to select the list of rpms you want to include at the time of installation

Select the list of packages from the below shown options

Click **Next** to start the installation

Once the installation is done. Click on **reboot** to move ahead with the installation process as yet your Linux is not completely installed. Still some initial configuration is pending

Click on **Forward**

Accept the **License and Agreement**

You can enable or disable the firewall using the drop down menus. Also you have option to enable selective services through the firewall for your server as shown below

You can choose to enable or disable **SELinux**

If you want you can enable **Kdump** by checking the below check box

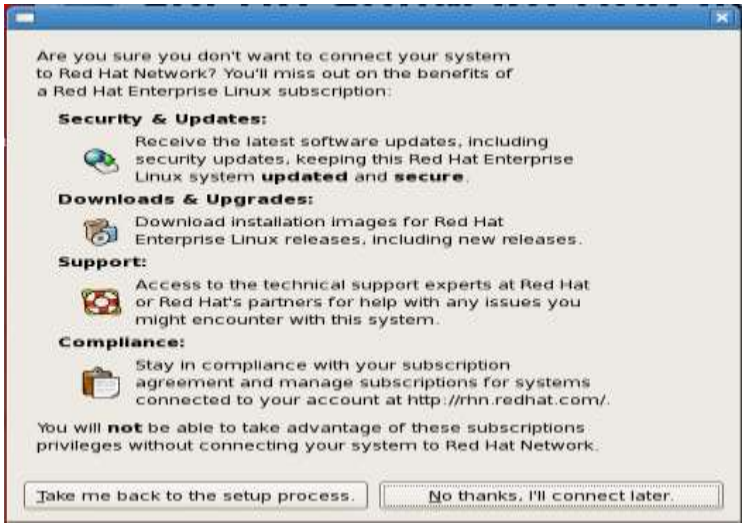

Set the **date and time**

In this step you can register your server with RHN so that it can get regular updates for all the patches and bug fixes regularly. As of now we will skip registering, I will show you to do the same from terminal in my next post.

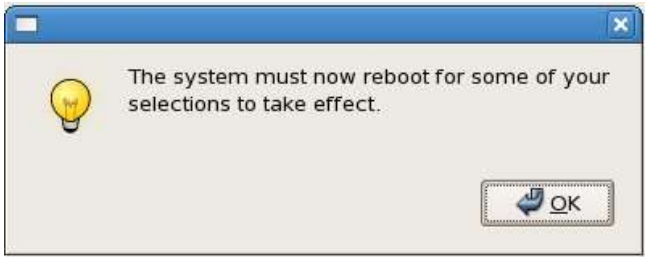

In this step you can create a user(optional)

Since you made changes in **SElinux** settings, the system will go for a reboot to take the changes affect

After the reboot your system is ready for use
